

FISH STOCK ASSESSMENT SURVEY IN SUBAREA 48.3

I. Everson¹, G. Parkes², K.-H. Kock³, S. Campbell¹, Z. Cielniaszek⁴ and J. Szlakowski⁴

Abstract

A demersal fish survey in the vicinity of South Georgia, CCAMLR Subarea 48.3, is described. Details are given of positions of hauls, catch rates and size composition of catches. The standing stock of one of the most important commercial species in the area, *Champocephalus gunnari*, is shown to have undergone a major decline by comparison with results from the 1989/90 season. Other species do not show a similar dramatic reduction. No commercial fishing on *Champocephalus gunnari* has been reported from the area. It is suggested that this decline may be due to either a massed migration or high mortality.

Résumé

Description d'une campagne d'évaluation des poissons démersaux aux environs de la Géorgie du Sud, sous-zone 48.3 de la CCAMLR. Précisions sur la position des chalutages, les taux de capture et la composition en taille des captures. Il est révélé que le stock existant de l'une des espèces commerciales les plus importantes dans la région, *Champocephalus gunnari*, a subi un déclin considérable par comparaison aux résultats de la saison 1989/90. D'autres espèces ne paraissent pas présenter une réduction aussi notable. Aucune pêche commerciale de *Champocephalus gunnari* n'a été déclarée dans la région. Il est suggéré que ce déclin pourrait avoir deux causes possibles : une migration de masse ou une mortalité élevée.

Резюме

Описана съемка демерсальных рыб вблизи Южной Георгии, Подрайон АНТКОМа 48.3. Приведена информация о положениях тралений, темпах вылова и размерном составе уловов. Выявлено значительное уменьшение биомассы одного из наиболее важных коммерческих видов этого района, *Champocephalus gunnari*, по сравнению с результатами сезона 1989/1990 г. Подобного драматического уменьшения в запасах других видов не обнаружено. Поскольку сведений о коммерческом промысле *Champocephalus gunnari* из этого района не поступало, предполагается, что упадок мог произойти вследствие массовой миграции или высокой смертности рыб.

Resumen

En este documento se describe una prospección de peces demersales realizada cerca de Georgia del Sur, en la Subárea 48.3 de la CCRVMA, y se proporcionan detalles de la posición de los lances, índices de capturas y composición por talla de las capturas. Al comparar la población fija de una de las especies comerciales más importantes de este área, *Champscephalus gunnari*, con los resultados de la temporada 1989/90, se observa que ha ocurrido una gran disminución. Otras especies no presentan una reducción tan drástica. No se ha notificado ninguna pesquería comercial de *C. gunnari* en esta zona. Se sugiere que esta disminución puede deberse a una migración masiva o a una alta mortalidad.

1. INTRODUCTION

The fish stocks in Subarea 48.3, South Georgia, have been the subject of considerable interest for many years mainly because this area has formed the focus for much of the commercial fishing activity for finfish within the CCAMLR area. The need for further assessment of the stocks within this subarea has been emphasised by the CCAMLR Working Group on Fish Stock Assessment (WG-FSA) (SC-CAMLR, 1990a).

This report presents the results from a fish stock assessment survey undertaken by the United Kingdom in January and February 1991 within Statistical Subarea 48.3 (South Georgia). The main aim of the study was to determine the standing stock of the commercially important demersal fish species with particular reference to the icefish, *Champscephalus gunnari*. Information is presented in accordance with the recommendations of the Task Group for Information Reported to WG-FSA (SC-CAMLR, 1990a).

2. SURVEY AREA AND DESIGN

The survey was aimed at providing information representative of the shelf area within Subarea 48.3. Effectively this is the shelf area of South Georgia and Shag Rocks.

The survey design was similar to those of previous years (Parkes *et al.*, 1990) with a series of randomly located trawl stations down to a depth of 500 m. The same three depth strata, 50 to 150, 150 to 250 and 250 to 500 m, were used as on previous surveys. To ensure adequate coverage the area was divided into CCAMLR 'fine-scale rectangles' half a degree of latitude by one degree of longitude. Within each of these rectangles the numbers of stations within each of these depth strata were allocated in proportion to the area of seabed and expected fish concentration of *Champscephalus* within the stratum. Wherever possible proposed trawling locations were chosen from those successfully sampled on previous surveys. Sampling locations were allocated to all fine-scale rectangles with the exception of those to the south of the centre of South Georgia. These three rectangles, numbers 19, 20 and 24 on Figure 1, are known to contain large areas of bad ground and thus have a high risk of trawl damage.

The survey design provided for 72 stations to be sampled at South Georgia and 12 at Shag Rocks. Due to time constraints and also because some intended sites were unsuitable for fishing not all sites were fished. A total of 66 sites was fished at South Georgia and 12 at Shag Rocks. The locations of the sites actually sampled are shown in Figure 1 and the positions given in Table 1. The mean area assumed to be representative of a station within each depth stratum and at each location is shown in Table 2.

A standard haul duration of 30 minutes with the net on the bottom was used. However if the net came fast, or bad ground was encountered during the tow necessitating early retrieval of the net, providing the net had been on the bottom for more than fifteen minutes the haul was considered representative. All hauls were undertaken during the hours of daylight to minimise the possible underestimation of those species that migrate off the bottom at night.

3. DESCRIPTION OF VESSEL AND SAMPLING METHODS

A stern trawler converted for use as a fishery survey vessel was used for the survey, it had the following characteristics:

Name:	<i>Falklands Protector</i>
Call sign:	GYMA
Type:	Stern trawler (modified by conversion of part of hold to laboratories)
Length overall:	69.15 m
Breadth:	12.0 m
Main Power	2500 bhp

Two echosounders were used during the study. A Kelvin Hughes MS 44 echosounder operating at a nominal frequency of 30 kHz was used for bottom detection and a Kodan 'Chromascope' operating at 48 kHz was used to indicate the hardness of the bottom. The latter echosounder was also connected to a Biosonics Echosignal Processor for fish quantification and was continually monitored for the presence of schools of fish above the bottom.

A net as close as possible to that used for the *Professor Siedlecki* survey (Parkes *et al.*, 1989) in 1989 was used, full net drawings with nominal mesh sizes are given in Figure 2. All netting was composed of diamond meshes. Mesh sizes were measured, in accordance with CCAMLR procedures, at the end of the survey and the results set out in Table 3. Field trials undertaken by the Sea Fisheries Industry Authority (UK) provided data on the dimensions of the trawl when in operation and these were latter confirmed by tests in a flume tank on a model of the trawl. Equations relating the principal dimensions to the towing speed are as follows:

$$A = [-2.295 S] + [-78067 (S^{-10})] + 29.08$$

where A = horizontal opening (m), and

S = towing speed (knots)

Positions were fixed using either Global Positioning System (GPS) or by satellite navigator. Satellite navigator fixes were available at irregular intervals of up to six hours. The GPS was operational for only part of the cruise and then, because of the incomplete satellite cover, only for about half the day.

The landed catch of all fish species at each station was measured. Further analyses were made for the following species: *Champscephalus gunnari*, *Chaenocephalus aceratus*, *Pseudochaenichthys georgianus*, *Notothenia gibberifrons*, *Notothenia rossii*, *Notothenia squamifrons*, *Dissostichus eleginoides* and *Patagonotothen brevicauda guntheri*. Total length (to the nearest centimetre below), sex and maturity (SC-CAMLR, 1989) were determined for a representative sample of fish of these species in the catch. Weight, stomach fullness, otoliths and, where possible, scales, were also taken for particular fish according a pre-determined sampling scheme. Otoliths were read at the Sea Fisheries Institute in Poland.

4. RESULTS

4.1 Distribution of Catches

All species were identified in the catches. Samples of catches from the following species of current or recent commercial importance, *C. gunnari*, *C. aceratus*, *P. georgianus*, *N. gibberifrons*, *N. rossii*, *N. squamifrons*, *D. eleginoides* and *P. b. guntheri*, were analysed. This involved measurement of length and weight, estimation of sex, maturity stage and stomach fullness, extraction of otoliths and, where appropriate, scales. Other species were counted and their total weight measured.

The number of stations at which individual species were found and the total weight caught within each depth stratum are shown in Table 4 for South Georgia and Table 5 for Shag Rocks. The distribution of catch rates for the major species are shown in Figures 3 to 9.

Several species, *C. gunnari*, *C. aceratus*, *P. georgianus* and *N. gibberifrons*, were widespread around South Georgia, being found at nearly all stations. *N. rossii*, although present at most stations down to 250 m was caught in only one haul from water deeper than 250 m whilst *D. eleginoides* was only caught sporadically.

At Shag Rocks *C. gunnari* was caught at all stations shallower than 250 m while *D. eleginoides* was caught at all except one of the total stations sampled.

At 94% of the stations where it was caught, the catch rates of *C. gunnari* were less than 200 kg for a 30 minute tow. No aggregations suitable for commercial fishing were seen either at South Georgia or Shag Rocks. The two largest catches, one of 696 kg at Shag Rocks and the other of 336 kg from the eastern end of South Georgia, were still very small relative to previous surveys (SC-CAMLR, 1990a). At most stations where *C. gunnari* were caught there was generally an equal or even greater catch of other species.

A single large catch of 1 169 kg of *D. eleginoides* exceeded, by an order of magnitude, catches of this species elsewhere. Although present in all except one haul at Shag Rocks this species only occurred sporadically around South Georgia.

N. rossii was not present at Shag Rocks but was present at South Georgia, although at low catch rates in all except one instance, in hauls from water shallower than 250 m.

P. b. guntheri was taken in small amounts from hauls around Shag Rocks. As on all previous surveys, none were taken from the South Georgia shelf region.

4.2 Standing Stock Estimates

Examination of the distribution of catch rates indicated that there were no outlying values resulting from isolated large catches. There was therefore no need to apply a large haul adjustment (SC-CAMLR, 1990b) to the analyses. Standing stock estimates by the swept area method were made for the species of commercial importance by the same method as used in SC-CAMLR (1990a). The data were stratified by depth zone and for the two regions, South Georgia and Shag Rocks.

Standing stock estimates for the species of current or recent commercial interest are shown in Table 6 for South Georgia and Table 7 for Shag Rocks. The coefficients of variation of the estimates for South Georgia are much lower than from previous surveys indicating a much more uniform distribution with little tendency to aggregation.

4.3 Length to Weight Relationships

Length to weight relationships were determined from measurements made at sea for all the major fish species. The results are summarised in Table 8. Due to the increase in size of the gonads in the months prior to spawning the simple linear relationships set out in Table 8 are not valid necessarily for all sizes and maturity states of fish.

There are some differences between areas and for different maturity stages of the mackerel icefish, *C. gunnari*, and a full analysis for this species is planned.

The equations for *C. aceratus* are valid for most fish in the size range 12 to 72 cm. However, stage 2 and 3 males of length 46 to 56 cm and stage 3 females of 59 to 64 cm were significantly heavier than indicated by the simple logarithmic relationship.

Similar increases were noted for *P. georgianus* where stage 2 and 3 males and females greater than 46 cm total length were heavier than indicated by the equations.

4.4 Length and Age Distributions

Aggregated length distributions for the eight species sampled on the survey are presented in Figures 10 to 17. These have been calculated by weighting the length distributions by the catch-per-unit-effort (total area swept by the net) prior to summing across the stations (equation 1 in Parkes, 1991b).

For *C. gunnari* at South Georgia there is a clear modal peak at 16 cm and a second, less distinct peak at 23 cm (Figure 10). There is no distinct mode for fish >25 cm as there was in last year's survey (Parkes *et al.*, 1990). By contrast, at Shag Rocks two distinct modal values were present at 26 and 32 cm and few small fish were present (Figure 11).

An age/length key was prepared using age data derived from otoliths. Unfortunately, no fish of either 18 or 19 cm were sampled for otoliths. Use of the age/length, in its raw format, would give rise to misleading results because fish of length 18 and 19 cm would not be allocated an age class. Combining the length distributions of *C. gunnari* from Shag Rocks and South Georgia indicates that there is a well defined peak extending from 11 to 20 cm, with a peak at 16 cm and a trough at 20 cm. We have therefore adjusted the age/length key prepared from the raw data by allocating fish of length 18 and 19 cm to age class 1. The revised age/length key, including the values for 18 and 19 cm fish shown in parenthesis, is shown in Table 9. In this form it gives a 'knife-edge' change from age class 1 to age class 2 at 20 cm, which coincides with the trough in the length distribution.

The length frequency distribution for *C. aceratus* (Figure 11) shows modal values at 17, 26, 32 and 49 cm. There are no distinct modes for larger fish due to dimorphic growth rates. Two clear modes, at 24 and 36 cm, are also present for *P. georgianus*.

The distribution for *D. eleginoides* has several modes which are indicative of year classes, these have been analysed further by Everson (1991).

The distributions for *N. rossii* and *N. gibberifrons* each have several peaks although none are sufficiently pronounced to indicate year classes reliably.

Ages of individual fish have been determined from otolith and scale readings and these have been used to provide age distributions in terms of numbers and biomass. The results are shown in Tables 10 and 11.

The data from the age and length distributions have been combined to provide mean length and mean weight at age, these are presented in Tables 12 and 13. All the calculations use

overall age/length keys and, in the case of the mackerel icefish, *C. gunnari*, all fish of length 18 and 19 cm have been assigned to age 1 (SC-CAMLR 1991).

The results for the mackerel icefish, *C. gunnari*, are considered further in a separate paper (Parkes, 1991c).

4.5 Maturity Stages

The length at which 50% of the population are sexually mature, L_{50} , has been derived from the logistic equation used in Everson *et al.* (1991) from samples examined during the survey. The results are given in Table 14. Even though this year's survey was slightly later in the year than the 1990 survey the results are broadly similar for most species.

For *C. gunnari* many of the Stage 2 ovaries looked abnormal and samples were collected for histological examination. A preliminary report is presented in a separate paper (Everson *et al.*, 1991).

4.6 Stomach Contents

The level of stomach fullness from samples examined was estimated and categorisation of the dominant food items was made for the major species. Krill, which have been a major component in the diet of *C. gunnari* in previous years, were rarely the dominant component of the diet in the stomachs examined. The results from this study are examined in a separate paper (Kock *et al.*, 1991).

4.7 Acoustic Observations

Each trawling site was monitored acoustically during the course of the haul, no indications were seen that indicated the presence of large schools of fish. In addition, most trawling sites were examined prior to hauls being made either during the hours of darkness or immediately in advance of fishing. No large schools of fish were detected during these investigations.

5. DISCUSSION

The standing stock estimates for all species, with the exception of *C. gunnari*, are broadly similar to those from the most recent surveys at South Georgia; these are compared in Table 15. A similar picture is not present for surveys at Shag Rocks (Table 16) probably because there are fewer species, fewer surveys and a many fewer hauls in that locality.

The estimated standing stock of *C. gunnari* from this year's survey is very much lower than that from either of the two independent surveys undertaken during 1989/90. It is however broadly similar to those from earlier years with the exception of 1985/86 when a totally different type of net was used.

Acoustic observations indicate that schools of *C. gunnari* were not present anywhere during the current survey, and, that those fish that were present were distributed more or less randomly in the area. Such a distribution would explain the low variance and CV of the standing stock estimate from the trawl survey. We therefore conclude that the standing stock during 1990/91 survey is substantially lower than that from the previous year and is not an artefact of the sampling technique or survey design.

Further evidence for this reduction is available from the commercial fishing fleets in the area. A single Polish trawler *Lepus* was operating in the area and reported catch rates of less than one tonne per day; after several days this vessel left the area. Several Russian trawlers reported to the Harbourmaster, South Georgia, that fishing for *C. gunnari* was extremely poor and that they would move to other grounds.

These observations provide support for the suggestion that there has been a significant reduction in the standing stock of *C. gunnari*. We consider three possible reasons for such a change:

- (a) intense fishing between February and December 1990;
- (b) migration from the area; and
- (c) unusually high natural mortality.

We know of no fishing activity in the area which could have accounted for such a large reduction in standing stock and therefore consider it highly unlikely that the first possibility is the cause.

Any migration would need to take the fish to an area of shelf some considerable distance away. The nearest such shelf area is in the South Orkneys, which, although remote, is not an impossible distance for the fish to migrate. Comparison with samples obtained in that area may confirm whether or not this has occurred.

The third possibility, that there has been an unusually high natural mortality, would be surprising but consistent with the season being characterised by poor krill availability affecting feeding (Kock *et al.*, 1991) and the fish undergoing abnormal gonad maturation processes (Everson *et al.*, 1991). We are investigating all three hypotheses.

ACKNOWLEDGEMENTS

The assistance of Alan Jagger, Master of *Falklands Protector*, and all the ship's company is gratefully acknowledged. Various items of equipment were kindly loaned by the Falkland Island Fisheries Department. The survey was funded by the South Georgia Commission.

Liste des tableaux

- Tableau 1: Heures (GMT - 3 heures) et localisation des stations échantillonnées.
- Tableau 2: Couverture de l'échantillonnage effectué autour de la Géorgie du Sud et des îlots Shag.
- Tableau 3: Taille du maillage du chalut de fond utilisé pour la campagne d'évaluation dans la Géorgie du Sud en 1990/91.
- Tableau 4: Capture par espèce et nombre de stations auxquelles les espèces ont été capturées dans la région de Géorgie du Sud.
- Tableau 5: Capture par espèce et nombre de stations auxquelles les espèces ont été capturées dans la région des îlots Shag.
- Tableau 6: Estimations de biomasse des espèces les plus communes aux alentours de la Géorgie du Sud, calculées par la méthode de l'aire balayée. CV = coefficient de variation de l'estimation (Saville, 1977).
- Tableau 7: Estimations de biomasse des espèces les plus communes aux alentours des îlots Shag, calculées par la méthode de l'aire balayée. CV = coefficient de variation de l'estimation (Saville, 1977).
- Tableau 8: Rapports longueur/poids à partir des mensurations obtenues pendant la campagne d'évaluation; longueur en cm, poids en g, (régression linéaire des moindres carrés sur les données après transformation \log_e).
- Tableau 9: Clé âge/longueur pour *C. gunnari*, calculée à partir de lectures d'otolithes de la campagne d'évaluation du *Falklands Protector* de janvier/février 1991, augmentée pour allouer les longueurs de 18 et 19 cm à la classe d'âge 1. Les chiffres entre parenthèses ont été ajoutés selon les explications de la section 4.4 du présent rapport.
- Tableau 10: Structure d'âge de la capture (% du nombre) d'après les échantillons prélevés pendant la campagne pour déterminer la longueur, le poids et l'âge. Sauf indication contraire, toutes les valeurs sont données pour la Géorgie du Sud, et pour les deux sexes.
- Tableau 11: Structure d'âge de la capture (% de la biomasse) d'après les échantillons prélevés pendant la campagne pour déterminer la longueur, le poids et l'âge. Sauf indication contraire, toutes les valeurs sont données pour la Géorgie du Sud, et pour les deux sexes.
- Tableau 12: Longueur moyenne (cm) selon l'âge des échantillons de longueur et d'âge prélevés pendant la campagne. Sauf indication contraire, toutes les valeurs sont données pour la Géorgie du Sud.
- Tableau 13: Poids moyen (g) selon l'âge des échantillons de longueur et d'âge prélevés pendant la campagne. Sauf indication contraire, toutes les valeurs sont données pour la Géorgie du Sud.
- Tableau 14: Longueur à laquelle 50% de la population a atteint la maturité sexuelle (L_{50}) et pourcentage de poissons par stade de maturité à partir des échantillons rassemblés pendant la campagne. Sauf indication contraire, tous les résultats se rapportent à la Géorgie du Sud.

Tableau 15: Comparaison des estimations de biomasse (tonnes) avec les résultats de campagnes d'évaluation menées précédemment autour de la Géorgie du Sud, coefficient de variation (%) compris.

Tableau 16: Comparaison des estimations de biomasse (tonnes) avec les résultats de campagnes d'évaluation menées précédemment autour des îlots Shag, coefficient de variation (%) compris.

Список таблиц

Таблица 1: Время (по Гринвичу-3 часа) и местоположение станций.

Таблица 2: Площадь сбора проб вокруг Южной Георгии и скал Шаг.

Таблица 3: Данные по размеру ячеи донного трала, использованного в съемке на Южной Георгии в 1990/91 г.

- Таблица 4: Общий вылов и количество станций, на которых рыбы были выловлены в районе Южной Георгии.
- Таблица 5: Общий вылов и количество станций, на которых рыбы были выловлены в районе скал Шаг.
- Таблица 6: Оценки биомассы наиболее часто встречающихся вокруг Южной Георгии видов, вычисленные "методом протраленных площадей". CV - коэффициент изменчивости оценки (Saville 1977).
- Таблица 7: Оценки биомассы наиболее часто встречающихся вокруг скал Шаг видов, вычисленные "методом протраленных площадей." CV - коэффициент изменчивости оценки (Saville 1977).
- Таблица 8: Взаимоотношения длина/вес по измерениям, сделанным в течение съемки; длина в см., вес в гр., (уравнение регрессии наименьших квадратов, построенное по \log_e -трансформированным данным).
- Таблица 9: Размерно-возрастной ключ для *C. gunnari*, приготовленный по анализу отолитов в ходе съемки *Falklands Protector* в январе-феврале 1991 г., увеличенный в целях размещения длин 18 и 19 см. в возрастной класс 1. Цифры в скобках были добавлены как объяснено в части 4.4 настоящей работы.
- Таблица 10: Возрастное распределение улова (количество-%) для проб длины, веса и возраста, взятых во время съемки. Все величины относятся к Южной Георгии и обоим полам, за исключением выделенных.
- Таблица 11: Возрастное распределение улова (биомасса-%) для проб длины, веса и возраста, взятых во время съемки. Все величины относятся к Южной Георгии и обоим полам, за исключением выделенных.
- Таблица 12: Средняя длина (см) при возрасте для проб длины и веса, взятых во время съемки. Все величины относятся к Южной Георгии, за исключением выделенных.
- Таблица 13: Средний вес (гр.) при возрасте для проб длины и веса, взятых во время съемки. Все величины относятся к Южной Георгии, за исключением выделенных.
- Таблица 14: Длина, при которой 50% популяции достигло половой зрелости (L_{50}), и процентное содержание рыб в стадии половозрелости. Пробы были взяты во время съемки. Все результаты относятся к Южной Георгии, за исключением выделенного.
- Таблица 15: Сравнение оценок биомассы (в тоннах) с результатами предыдущих съемок вокруг Южной Георгии, включая коэффициент изменчивости (%).
- Таблица 16: Сравнение оценок биомассы (в тоннах) с результатами предыдущих съемок вокруг скал Шаг, включая коэффициент изменчивости (%).

Lista de las tablas

- Tabla 1: Horas (GMT-3 horas) y posición de las estaciones de muestreo.
- Tabla 2: Cobertura de muestreo alrededor de Georgia del Sur y de las rocas Cormorán.
- Tabla 3: Mediciones de la luz de malla del arrastre de fondo empleado en la prospección de Georgia del Sur en 1990/91.

- Tabla 4: Captura total y número de estaciones donde se capturaron las especies de la región de Georgia del Sur.
- Tabla 5: Captura total y número de estaciones donde se capturaron las especies de la región de las rocas Cormorán.
- Tabla 6: Estimaciones de biomasa de las especies más comunes alrededor de Georgia del Sur, calculadas utilizando el 'método de área barrida'. CV= coeficiente de variación de la estimación (Saville 1977).
- Tabla 7: Estimaciones de biomasa de las especies más comunes alrededor de las rocas Cormorán, calculadas utilizando el 'método de área barrida'. CV= coeficiente de variación de la estimación (Saville 1977).
- Tabla 8: Razón longitud/peso de las mediciones hechas durante la prospección; longitud en cm; peso en g, (regresión lineal de los mínimos cuadrados de los datos transformados a \log_e).
- Tabla 9: Clave de edad/talla para *C. gunnari* deducida de los registros de otolitos obtenidos de la prospección realizada por el *Falklands Protector* durante enero/febrero de 1991, aumentada para asignar las tallas de 18 y 19 cm a la clase anual 1. Los números en paréntesis se han sumado de acuerdo a la explicación en la sección 4.4 de este informe.
- Tabla 10: Distribución de edades de la captura (porcentaje) de las muestras tomadas durante la prospección para medir la longitud, peso y edad. Todos los valores son para Georgia del Sur y para ambos sexos, excepto donde se indica.
- Tabla 11: Distribución de edades de la captura (% biomasa) de las muestras tomadas durante la prospección para medir la longitud, peso y edad. Todos los valores son para Georgia del Sur y para ambos sexos, excepto donde se indica.
- Tabla 12: Longitud media (cm) a la edad de las muestras tomadas durante la prospección para medir la talla y edad. Todos los valores son para Georgia del Sur, excepto donde se indica.
- Tabla 13: Peso medio (g) a la edad de las muestras tomadas durante la prospección para medir la talla y edad. Todos los valores son para Georgia del Sur, excepto donde se indica.
- Tabla 14: Talla cuando el 50% de la población alcanza la madurez sexual (L_{50}) y porcentaje de peces de acuerdo a la fase de madurez de las muestras tomadas durante la prospección. Todos los resultados se refieren a Georgia del Sur, a menos que se indique lo contrario.
- Tabla 15: Comparación de las estimaciones de biomasa (toneladas) con los resultados obtenidos de las prospecciones anteriores realizadas alrededor de Georgia del Sur, incluyendo el coeficiente de variación (%).
- Tabla 16: Comparación de las estimaciones de biomasa (toneladas) con los resultados obtenidos de las prospecciones anteriores realizadas alrededor de las rocas Cormorán, incluyendo el coeficiente de variación (%).
